Abstract The effect of insulin on interleukin 2 (IL-2) production was investigated. The results showed that insulin alone did not stimulate the resting T lymphocytes to produce IL-2, but enhanced the production of IL-2 by T lymphocytes and interleukin 1 (IL-1) by macrophages in the presence of lectin. Insulin augmented the response of T lymphocytes to IL-1 in the presence of Con A. The peak time of IL-2 production was not affected by insulin.

Key words: insulin; interleukin 2; interleukin 1; T lymphocytes; macrophages

Insulin, a polypeptide hormone, plays an important role in immune regulation, such as enhancement of lymphocyte activation, cytotoxic response of T cells and mixed lymphocyte cultures (MLC) reaction in vitro etc. As so far, it was not known how insulin regulates lymphokins. In this paper, we present evidence that insulin enhances IL-2 production in the presence of lectin and the mechanism for regulation of insulin on T lymphocyte activation is analyzed.

Materials and methods

Human peripheral blood The peripheral blood of healthy volunteers was obtained from Wuhan Blood Centre. The blood was defibrinated using sterile glass beads.

Mice C 57 BL/6 mice, 6 to 8-wk-old (for obtaining peritoneal macrophages) and 3 to 4-wk-old (for obtaining thymocytes), were obtained from Experimental Animal Centre of Tongji Medical University.

Insulin Crystaline insulin (purchased from Shanghai Chemical Reagent Store) was dissolved in RPMI 1640 (pH 7.0) and
stored for no longer than 1 wk at 4°C.

Preparation of human IL-2 Human peripheral blood lymphocytes (HPBL) were isolated from defibrinated blood by Ficoll- Hypaque density centrifugation. The cells were suspended in a cell density of 2x10^6 cells/ml in RPMI 1640 supplemented with 1.5% human serum and purified phytohemagglutinin (PHA-P, Difco) 10 μg/ml in absence of presence of insulin, and then cultured in 24-well culture plates (Costar) at 37°C, in 5% CO2 with a humid atmosphere. After 48 to 44 h, supernatants were collected by centrifugation (600 x g for 20 min) and stored at -20°C until assay for IL-2 activity. The supernatants were designated as human peripheral blood lymphocyte conditioned medium (HPBL-CM).

Assay for IL-2 activity T lymphoblasts were isolated from HPBL stimulated with PHA-P for 4 d by Ficoll-Hypaque density centrifugation, and cultured in 96-well culture plate (Costar) at a cell density of 2x10^5 cells/well in absence or presence of HPBL-CM. After 64 h, the culture was pulsed with [3H]TdR (0.01 μCi/well) for 6 h. The cells were harvested onto glass fiber filters with cell harvester, and [3H]TdR incorporation was determined by liquid scintillation counting. The results were expressed as the ratio of cpm of [3H]TdR in triplicate cultures.

Preparation of mouse IL-1 Mouse IL-1 was prepared as reported earlier. Briefly, peritoneal macrophages from 6 to 8-wk-old mice were cultured at a cell density of 1x10^6 cells/ml in RPMI 1640 supplemented with 10% lipopolysaccharide (LPS, Sigma) and 10% new born calf serum (NBCS) in the presence or absence of insulin in 96-well culture plates. After 48 h, the supernatants were collected by centrifugation and stored at -20°C until assay for IL-1 activity. The supernatants were designated as Mφ-CM.

Assay for IL-1 activity Thymocytes from 3 to 4-wk-old mice were treated with nylon wool to remove the adherent cells and cultured in 96-well culture plate (5 x 10^6 cells/well) in RPMI 1640 supplemented with 15% NBCS in the presence of 5 μg/ml Con A and Mφ-CM. After 60 h, thymocyte cultures were pulsed with 0.018 MBq of [3H]TdR for 16 h. The cells were harvested onto glass fiber filters and [3H]TdR incorporation was determined as above.

Results

Effect of insulin on IL-2 production The ability of IL-2 production by T cells stimulated with PHA and/or insulin was tested. The insulin preexposed in HPBL-CM wouldn't influence the result of assay of IL-2 activity, because insulin is inactive after incubated at 37°C for 48 h and cryopreserved at -20°C (data not shown). As shown in table 1, insulin did not trigger the resting T lymphocytes to produce IL-2 if PHA was absent, but enhanced IL-2 production by T cells in the presence of PHA. The action of insulin to enhance IL-2 production was augmented with dose of insulin increased (Fig 1).

![Fig 1](image-url)
It was reported that insulin replaced to mitogen to maintain the proliferative response after removal of mitogen. To investigate the mechanism of insulin action, the following experiment was performed. HPBL was cultured in RPMI 1640 medium with PHA-P 10 μg/ml and 10% human serum for 12 h, then washed three times to remove PHA and recultured in RPMI 1640 medium with 10% human serum at 37 °C. The culture supernatants were collected at 24 h and 60 h. Insulin activity was assayed (Tab. 2). Insulin replaced to maintain the continuation of IL-2 production by lymphocytes after removal of PHA. IL-2 activity of insulin group was higher than that of control group.

**Fig. 2. Kinetics of IL-2 production in the presence (○) or absence (□) of insulin. n = 4, X ± SD. ***P < 0.01 vs control.**

Effect of insulin on peak hours of IL-2 production. HPBL was stimulated by PHA in the presence or absence of insulin, and the culture supernatants were collected at different times. IL-2 activity in supernatants was assayed. Fig 2 shows that the kinetics of IL-2 production in the presence of insulin was the same as that in the absence of insulin. But IL-2 activity of insulin group was higher than that of control group at different times, indicating that insulin enhanced IL-2 production, but did not change the peak time of IL-2 production.

Effect of insulin on production and action of IL-1 Peritoneal macrophages from mice were stimulated with LPS for 48 h in the presence or absence of insulin, and the IL-1 activity in the supernatants was assayed. Insulin was added in the system to observe the effect of insulin on the action of IL-1. Table 3 showed that [3H]TDR uptake by thymocytes in insulin treatment.
groups (no matter whether insulin was added in preparation or in assay) was significantly higher than that of control group. Indicating that insulin augmented the production of IL-1 by macrophages and enhance the response of thymocytes to IL-1.

Discussion

In previous study, insulin was not found to be mitogen of lymphocytes\(^1\),\(^2\),\(^3\), but enhanced the activation of T lymphocytes in the presence of mitogens. We found that IL-2 activity in the culture supernatants did not be detected if the resting T lymphocytes were stimulated with insulin alone for 48 h. The possible reason for the result could be due to the lack of specific receptor for insulin on the resting lymphocyte surface\(^4\). Once the resting lymphocytes stimulated by mitogen expressed receptors for insulin, insulin-regulated metabolism of T cells through an initial interaction with a specific surface receptor and enhanced IL-2 production, even if mitogen was removed. Although insulin enhanced IL-2 production, but it did not change the peak time of IL-2 production. These results indicate that insulin is a regulating factor but not a factor triggering IL-2 synthesis by T lymphocytes.

Our experiment results demonstrated that thymocytes proliferated in the presence of exogenous IL-1 after stimulation by Con A, even if adherent cells was removed by the treatment with nylon wool. Under these conditions insulin increased \(^2\)H\(_{\text{TDR}}\) uptake by thymocytes, suggesting that insulin augmented response of thymocytes to IL-1.

IL-1 is required for the production of IL-2\(^5\),\(^6\). In this paper, we demonstrated that insulin enhanced IL-1 production by macrophages. The results obtained suggest that the effect of insulin on IL-2 production must be multiplicity. which included the effect of insulin on IL-1 production and the direct action of insulin on T cells. Enhancement by insulin of IL-2 production can be one of the mechanisms that insulin enhances the activation of T cells.

Data from experiments in which insulin regulated immune function in vitro led us to propose that in vivo hyposecretion of insulin must result in the decline of T lymphocyte-mediated immune function, which is a possible reason for immune abnormalities in diabetic animal\(^7\),\(^8\). The administration of insulin is surely to alleviate metabolic state as well as to strengten the capacity of immune functions of diabetes.

胰岛素对T淋巴细胞产生白细胞介素2的影响

罗 戴、冯作化、王蕊蕊、陈光丽

提要：胰岛素（10 μg/ml）本身不能刺激除T细胞外的细胞产生白细胞介素2（IL-2），但在此振荡存在时，胰岛
素可刺激T细胞产生IL-2，而不影响IL-2的产生高峰时间，可延长此高峰，胰岛素对抑制肿瘤细胞产生白
细胞介素2（IL-2）和抑制抗原刺激对IL-2的抑制，因此胰岛素可能通过IL-2细胞代谢的直接作用和增加巨噬
细胞IL-2的分泌来促进T细胞IL-2的产生。
