**KEY WORDS** cultured cells; neurons; calcium; cerebral cortex; arcuate nucleus; glutamates; *Ginkgo biloba*; ginkgolide B; quercetin

**AIM:** To determine whether the extract of leaves of *Ginkgo biloba* L. (EGB) and several active constituents of EGB have protective effects against glutamate (Glu)-induced neuronal damage.

**METHODS:** Microscopy and image analysis of nucleus areas in the arcuate nuclei (AN) of mice were made. The neuronal viability in primary cultures from mouse cerebral cortex was assessed using MTT [3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyl tetrazolium bromide] staining and the intracellular free calcium concentration ([Ca^{2+}]_i) of single neuron was measured using Fura-2.

**RESULTS:** EGB (2.5 mg·L^{-1}) and its constituent ginkgolide B (Gin B, 2 mg·L^{-1}) protected the neuronal viability against Glu-induced injury, and prevented the Glu-induced elevation in [Ca^{2+}]_i. EGB (3 – 10 mg·kg^{-1}) attenuated the decrease of nucleus areas in arcuate nuclei induced by Glu (1 g·kg^{-1}, sc). **CONCLUSION:** EGB and Gin B prevent neurons from Glu neurotoxicity through reduction of the rise in [Ca^{2+}]_i.

Glutamate neurotoxicity (GNT) participated in the neuron loss associated with a number of neurodegenerative diseases, e.g., Alzheimer’s disease and Huntington’s disease\(^{1,2}\). To investigate the GNT and anti-GNT drugs, a primary cell culture system derived from fetal mouse neocortex was used. In vivo studies were to detect the effects on arcuate nucleus in hypothalamus, which were fully protected by the blood-brain barrier (BBB) in immature animals\(^{3}\).

Overactivation of Glu receptors caused an excessive influx of Ca^{2+} into the neuron, which resulted in activation of lipase, protease, and protein kinase C, subsequently led to the generation of fatty acids, free radicals, and ultimately neural death. Ca^{2+} overloading and loss of Ca^{2+} homeostasis might play an important role in GNT\(^{4,5}\).

The extract of leaves of *Ginkgo biloba* L. (EGB) contained 24 % of flavonoid glycosides, the aglycon of which was a flavonol (including quercetin, kaempferol, and isorhamnetin), 6 % of terpene lactones (including ginkgolides A, B, C, I, and bilobalide), and 70 % of other substances (proanthocyanidins, organic acids, sugars, etc.)\(^{6}\). EGB had protective effects on GNT in a dose-dependent manner in both cultured mouse cortical neurons and cultured human hippocampal neurons\(^{7}\). This study was supported by the Natural Science Foundation of Jiangsu Province, No BK20030311.

Ginkgolide B

MATERIALS AND METHODS

Reagents  EGB was the product of Jarrow Formulas, Inc (Los Angeles CA, USA), which was analytically ensured to contain consistent of its composition, and standardized to contain 24% flavonol glycosides and 6% oleanolic acids. Ginkgolide B (Gin B, BN 52021, Rhône-Poulenc) was the product of Ipsen (30 rue Cambronne, Paris, France).

Quesnet (Qae), Fura-2, HEPES, and L-glutamic acid (L-Glu) were purchased from Sigma. L-Glu were dissolved in demineralized distilled water and adjusted to pH 7.0 with NH₄OH 1 mol L⁻¹. Dulbecco's modified Eagle medium (DMEM) and tetramethylthiazolyl-diphenyl-Tetrazolium (MTT) were purchased from Spino and Fluka, respectively. Other reagents were of AR grade. All solutions were prepared with deionized distilled water.

Primary cortical cell culture  Mouse cortical neurons were prepared from 14-17-d-old embryos using technique with minor modification[8]. The cerebral cortex was minced, triturated in 0.125% trypsin at 37°C for 10 min and stopped with Hank's balanced salt solution. The cell pellet was resuspended in DMEM supplemented with 20% heat-inactivated fetal bovine serum, L-Glu 2.0, NaHCO₃ 24, HEPES 10, and glucose 25 mmol L⁻¹. Cells were seeded at 2000 cells per well (3×10⁴ cells per well) coated with l-polylysine and incubated at 37°C in 5% CO₂ atmosphere. After 4-7 d in culture, non-neuronal cells division was halted by 1-3 d of exposure to cytosine arabinoside (10 μmol L⁻¹).

Culture medium was renewed every 3-4 d.

Treatment with Glu and EGB  Experiments were carried out after 7 d in culture. Following the incubation with EGB (2.5 mg L⁻¹), Qae (20 mg L⁻¹), and Gin B (2 mg L⁻¹) separately for 24 h, cell culture was exposed to Glu (0.5 mmol L⁻¹) at 25°C for 30 min, and then the solution was thoroughly washed and transferred to CO₂ incubator until the next day for MTT assay or microscopy.

**MTT stains**  MTT in PBS (0.1 mol L⁻¹, pH 7.2) 25 μL was added to each well of 96-well plates (1 g L⁻¹ final concentration) and incubated at 37°C for 4 h. The reaction was stopped by adding 100 μL lysing buffer (20% SDS in 50% N,N-dimethylformamide, pH 4.7). The absorbance was measured at 570 nm (A570) by microELISA reader after a further incubation at 37°C overnight[9].

**Image analysis**  Mice aged 7-9-d-old (n=42), weighing 5.4±0.6 g were divided into 6 groups at random. The mice were daily sc saline, Glu (1 g kg⁻¹), Glu + EGB (1, 3, 5, 7, 10 mg kg⁻¹) and EGB (1, 3, 5, 7, 10 mg kg⁻¹) for 7 d. EGB was injected 15 min before Glu. All mice were killed 1 wk after the final-treatment and perfused transcardially with 10% formalin, serial coronal sections (6 μm) were stained with cresyl violet[10]. Nucleus areas were determined by 540-Biological Medicine Color Image Analyser.

**Measurement of [Ca²⁺]i**  The freshly dissociated cortical neurons prepared from 1-2-d-old mice were loaded with Fura-2 AM 2 μmol L⁻¹ at 37°C for 45 min and collected by centrifugation. Cells were treated with Glu (100 μmol L⁻¹, 10 μL), Glu + EGB (1 g L⁻¹, 10 μL), or Glu + constituents of EGB, including Qae (0.8 g L⁻¹, 10 μL), Gin B (0.2 g L⁻¹, 10 μL), Que (0.8 g L⁻¹, 10 μL) + Gin B (0.2 g L⁻¹, 10 μL) in 100 μL suspension. [Ca²⁺]i was determined from the ratio of the fluorescence (λₐ = 340 and 380 nm; λₑ = 505 nm) by Spex AR-CM-MIC Cation Measurement System[11].

**Statistical analysis**  All data were presented as x±s. Comparisons between groups were made using t-test.

RESULTS

**GNT in vitro**  After 7 d in culture, neurons developed an extensive network, showing large and phase-bright cell bodies (Fig IA, Plate 2). When cultures were exposed to Glu, swelling and darkening of neurons were seen and debris or occurred in some areas (Fig IC). While sister cultures were exposed to EGB, Gin B, or Que for 1 d prior to Glu, it showed almost no (Fig ID) or a slight neuronal injury (Fig IE, IF).

This morphological change was confirmed by the assay of MTT (Tab 1).

Glu induced a marked decrease in A570, which can be completely abolished by the preincubation with EGB and Gin B + Que. When pretreated with the Que or Gin B, only the latter can partially abolish A570. Accordingly, Gin B may be a main active constituent in EGB to prevent GNT, while

Que enhances the protective effects of Gin B on GNT.

\([\text{Ca}^{2+}]_i\) of a normal neuron increased from the basal level of 279 ± 24 mmol·L⁻¹ to 388 ± 53 mmol·L⁻¹ after the addition of Glu (100 μmol·L⁻¹, 10 μL) into 100 μL suspension of neurons, which were reduced by the treatment of EGB, Gin B + Que, or Gin B alone (Tab 1).

**GNT in vivo**

As compared with the control group (Fig 2A), sc Glu (1 g·kg⁻¹) led to pyknotic nuclei and loss of neurons in the AN (Fig 2B), which were dramatically attenuated by sc EGB 10 mg·kg⁻¹ (Fig 2C).

Image analysis of the nucleus areas in the AN revealed that pretreatment of EGB (3 – 10 mg·kg⁻¹) dwindled the neuronal death induced by Glu in neonatal mice (Tab 2).

**DISCUSSION**

EGB, mainly its active constituents 24% flavonoid glycosides and 6% terpene lactones, could exert significant influences on cardiovascular system and CNS as a free radical scavengers and antagonist of PAF, while the effects of other 70% constituents are not identified(6). In the present experiments, using MTT assay, it was found that besides EGB, the active constituent Gin B alone or plus Que had significant protective effects on GNT, while the protective effect of Gin B + Que seemed to be greater than Gin B alone. Furthermore, similar results were obtained by the measurement of \([\text{Ca}^{2+}]_i\), excepted that Que had not shown any effects on \([\text{Ca}^{2+}]_i\). Que could directly inhibit NADPH diaphorase(13), which

Fig 2. Sections through arcuate nucleus of hypothalamus from mice treated with saline, Glu, and EGB + Glu daily for 7 d. A) normal neurons in arcuate nucleus after sc saline; B) pyknotic nuclei and loss of neurons in AN after sc Glu 1.0 g·kg⁻¹; C) less pyknotic nuclei and more neurons in AN after sc EGB (10 mg·kg⁻¹) 15 min before sc Glu, AN: arcuate nucleus, III: the 3rd ventricle.
distributes consistently with that of nitric oxide synthase, an important enzyme associated with GNT. So Que might probably help to attenuate GNT via inhibiting the production of NO in the brain. On the other hand, Ginkgolides (including A, B, C, and J) that are present in EGB possess 2, 3, or 4 hydroxyl function and may exist in a "cage-like" form, are specific and potent antagonists of PAF(6,12). The above findings of neuroprotection of Ginkgo B suggest that all ginkgolides might prevent GNT via the depression of the elevated level of Ca²⁺ induced by Glu, though the molecular mechanisms remain unknown.

In summary, both EGB 761 and Gin B may protect neurons against GNT by the suppression of the rise in [Ca²⁺].

ACKNOWLEDGMENTS We thank Dr YU Jun for his kind gifts of both EGB and Gin B.
