KEY WORDS 1-(2, 6-dimethylphenoxy)-2-(3, 4-dimethoxypheryl-ethylamino) propane hydrochloride; patch-clamp technique; myocardium; calcium channels; sodium channels; verapamil; mexiletine

ABSTRACT

AIM: To investigate the effects of 1-(2, 6-dimethylphenoxy)-2-(3, 4-dimethoxypheryl-ethylamino) propane hydrochloride (DDPH) on L-type calcium current (I_{Ca}) and sodium current (I_{Na}), and to compare its inhibitory potency with verapamil and mexiletine. METHODS: Whole-cell patch clamp technique was used to record I_{Ca} and I_{Na} in a single ventricular myocytes of guinea pig. RESULTS: (1) DDPH (3-300 μmol·L^{-1}) decreased I_{Ca} at 0 mV in a concentration-dependent manner with an IC_{50} value of 28.5 μmol·L^{-1} (95 % confidence limits: 14.3 - 42.7 μmol·L^{-1}, n = 8 cells from 8 guinea pigs). Verapamil (0.3 - 30 μmol·L^{-1}) reduced I_{Ca} with an IC_{50} value of 1.8 μmol·L^{-1} (95 % confidence limits: 1.3 - 2.3 μmol·L^{-1}, n = 6 cells from 6 guinea pigs). Mexiletine 100 μmol·L^{-1} did not affect I_{Ca} (n = 5 cells from 5 guinea pigs, P > 0.05). The degree of use-dependent blocking effect of DDPH 30 μmol/L on I_{Ca} was 58 ± 13 % (n = 5 cells from 5 guinea pigs, P < 0.01) at 1 Hz and 76 ± 11 % (n = 5 cells from 5 guinea pigs, P < 0.01) at 3 Hz. (2) DDPH (20 - 320 μmol·L^{-1}) could also block I_{Na} in a concentration-dependent manner with an IC_{50} value of 89.0 μmol·L^{-1} (95 % confidence limits: 68.7 - 109.3 μmol·L^{-1}, n = 9 cells from 9 guinea pigs). The IC_{50} value of mexiletine was 32.2 μmol·L^{-1} (95 % confidence limits: 11.7 - 52.7 μmol·L^{-1}, n = 5 cells from 5 guinea pigs). Verapamil at the concentration of 10 μmol·L^{-1} did not affect I_{Na} (n = 5 cells from 5 guinea pigs, P > 0.05). The blocking effect of DDPH 80 μmol/L on I_{Na} was non-use-dependent. CONCLUSION: DDPH exhibited inhibitory effects on both I_{Ca} and I_{Na}, but its inhibitory effect on I_{Ca} was weaker than verapamil, and on I_{Na} was weaker than mexiletine.

INTRODUCTION

1-(2, 6-Dimethylphenoxy)-2-(3, 4-dimethoxypheryl-ethylamino) propane hydrochloride (DDPH), is a new compound with chemical structure partly similar to that of verapamil and mexiletine. Our previous work demonstrated that DDPH could prevent arrhythmias induced by ischemia-reperfusion. DDPH also possessed anti-hypertensive effect, α₁-adrenoceptor blocking effect and calcium antagonistic effect. In the present study, we used whole-cell patch clamp technique to observe the effects of DDPH on I_{Ca} and I_{Na} in a single ventricular myocyte of guinea pigs and to compare its inhibitory potency with verapamil and mexiletine.

MATERIALS AND METHODS

Solutions and drugs DDPH was from China Pharmaceutical University (Nanjing). The stock solution (4 mmol·L^{-1}) was prepared with distilled water and the pH value was adjusted to 7.0 with NaOH. Tyrode’s solution contained (mmol·L^{-1}) NaCl 135, KCl 5.4, CaCl₂ 1.8, MgCl₂ 1.0, NaH₂PO₄ 0.33, glucose 10, and HEPES (Sigma) 10, with pH value 7.4. The ventricular myocyte dissociation solution was Ca²⁺-free Tyrode’s solution containing collagenase (type II, Sigma) 0.25 g·L^{-1}, protease E (Sigma) 0.25 g·L^{-1}, and bovine serum albumin (BSA) 0.25 g·L^{-1}. The intracellular solution consisted of (mmol·L^{-1}) CsCl 120, NaCl 10, CaCl₂ 1.0, Mg-ATP 5.0, eguanic acid (Sigma) 11, and HEPES 10, adjusted to pH 7.3 with CsOH.
cellular solution used to record \( I_{Na} \) contained (mmol·L\(^{-1}\)) choline chloride 100, NaCl 40, KCl 5.4, CaCl\(_2\) 1.0, MgCl\(_2\) 1.0, NaH\(_2\)PO\(_4\) 0.33, glucose 10, and HEPES 10, with the pH value 7.4.

**Cell isolation** Ventricular myocytes were obtained from the hearts of adult guinea pigs provided by the Medical Experimental Animal Center of Tongji Medical College of Huazhong University of Science and Technology (Grade II, Certificate No 19 - 025), using enzymatic dissociation method similar to that previously described\(^5\).

**Electric recordings** Whole-cell recordings were performed using an EPC 9 patch-clamp amplifier (HEKA, Germany). Myocytes were placed into a 1.5-mL chamber mounted on the stage of an inverted microscope (IX70, Olympus) and were superfused with Tyrode's solution. After a gigaseal (seal resistance 2 - 50 G\(\Omega\)) formation, the membrane was ruptured with gentle suction to obtain whole-cell voltage-clamp configuration. Thereafter, capacitance and series resistance compensations were optimized, usually 50 % - 80 % compensation was obtained. The current was filtered at 2.9 kHz and then stored on hard disk for subsequent analysis. Data acquisition and command potentials were controlled with a commercial software program (pCLAMP 6.0). The pipette resistance was 2 to 4 M\(\Omega\) when the pipette was filled with the intracellular solution and immersed into Tyrode's solution. To record \( I_{Na} \), the temperature was maintained at 19 °C and the pipette resistance was kept less than 1 M\(\Omega\) for better voltage control\(^5\).

**Statistical analysis** Values were expressed as \( x \pm s \). Statistic significance was determined by a unpaired \( t \)-test. The Marquardt-Levenberg method of nonlinear regression analysis was used to fit the concentration-response curves and to calculate the IC\(_{50}\) value according to the equation, \( I = I_{max}/(IC_{50}/[ C ] + 1) \).

**RESULTS**

**L-type calcium current (\( I_{Ca} \))** Recordings were obtained 5 min after the rupturing of the membrane. The peak whole-cell \( I_{Ca} \) was measured during a 200-ms depolarizing pulse to 0 mV after a 100-ms period at a holding potential of -40 mV at 0.1 Hz. DDPH (3 - 300 \( \mu \)mol·L\(^{-1}\)) blocked the \( I_{Ca} \) in a concentration-dependent manner with an IC\(_{50}\) value of 28.5 \( \mu \)mol·L\(^{-1}\) (95 % confidence limits: 14.3 - 42.7 \( \mu \)mol·L\(^{-1}\), \( n = 8 \) cells from 8 guinea pigs) (Fig 1). Verapamil had a similar but stronger blocking effect on the \( I_{Ca} \), with an IC\(_{50}\) value of 1.8 \( \mu \)mol·L\(^{-1}\) (95 % confidence limits: 1.3 - 2.3 \( \mu \)mol·L\(^{-1}\), \( n = 6 \) cells from 6 guinea pigs). Our experiment showed that methylineline, a class Ia antiarrhythmic agent, 100 \( \mu \)mol·L\(^{-1}\) reduced the IC\(_{50}\) from -549 pA ± 156 pA to -399 pA ± 176 pA (\( n = 5 \) cells from 5 guinea pigs, \( P > 0.05 \)). When the myocytes were voltage-clamped from -40 mV to different membrane potentials ranging from -40 mV to +50 mV in 10-mV steps at 0.1 Hz, the voltage-dependent \( I_{Ca} \) was recorded. DDPH at the concentration of 30 \( \mu \)mol·L\(^{-1}\) decreased peak \( I_{Ca} \) with no shift of the maximum activation potential of about 0 mV, where the peak \( I_{Ca} \) decreased from -758 pA ± 222 pA to -404 pA ± 149 pA (\( n = 6 \) cells from 6 guinea pigs, \( P < 0.01 \)) (Fig 2). Verapamil had use-dependent blocking effect on \( I_{Ca} \)\(^5\). To test whether DDPH also possessed the use-dependent characteristics in its action, we elicited the \( I_{Ca} \) with 10 repetitive clamp steps from -40 mV to 0 mV for 200 ms at 1.0 and 3.0 Hz pacing
Fig 2. Voltage-dependent block of $I_{Ca}$ in guinea pig ventricular myocytes by DDPH. A) $I_{Ca}$ current traces before and after DDPH 30 μmol·L$^{-1}$ treatment. B) Current-Voltage relationship curve of $I_{Ca}$. ○: control. •: DDPH 30 μmol·L$^{-1}$. (n = 6 cells from 6 guinea pigs, ± ± s).

rates. The reduction of $I_{Ca}$ at the first pulse after DDPH was defined as the tonic block. The use-dependent block was determined by the reduction of $I_{Ca}$ at the end of the 10th pulse, where the reduction of $I_{Ca}$ reached steady state. The tonic block of DDPH 30 μmol·L$^{-1}$ at 1 Hz and 3 Hz was 56 % ± 13 % and 62 % ± 14 % (n = 5 cells from 5 guinea pigs), respectively. After exposure to DDPH 30 μmol·L$^{-1}$, the degree of use-dependent block was 58 % ± 13 % (P < 0.01) at 1 Hz, and 76 % ± 11 % (P < 0.01) at 3 Hz. The blocking effect at 3 Hz was stronger than that at 1 Hz (P < 0.05) (Fig 3A).

To further elaborate the use-dependence, the average beat-to-beat reduction of $I_{Ca}(U/I_{Na})$ during the 10-pulse train is shown in Fig 3B. In presence of DDPH 30 μmol·L$^{-1}$, the reduction at the 10th pulse was greater at 3 Hz than that at 1 Hz (n = 5 cells from 5 guinea pigs, P < 0.05), while the reduction at the 10th pulse on drug-free condition showed no difference between 1 Hz and 3 Hz (P > 0.05).

Sodium current ($I_{Na}$) To study the effect of DDPH on $I_{Na}$, we activated the whole-cell $I_{Na}$ with a 200-msec depolarization from a holding potential of −80 mV to −30 mV at 0.1 Hz. DDPH (20–320 μmol·L$^{-1}$) blocked the $I_{Na}$ in a concentration-dependent manner, with an $IC_{50}$ value of 89.0 μmol·L$^{-1}$ (95 % confidence limits: 68.7 − 109.3 μmol·L$^{-1}$, n = 9 cells from 9 guinea pigs) (Fig 4). The $IC_{50}$ value of mexiletine was 32.2 μmol·L$^{-1}$ (95 % confidence limits: 11.7 − 52.7 μmol·L$^{-1}$, n = 5 cells from 5 guinea pigs) (Fig 4). Verapamil 10 μmol·L$^{-1}$ reduced $I_{Na}$ from −9.6 nA ± 3.4 nA to −9.2 nA ± 3.3 nA (n = 5 cells from 5 guinea pigs, P > 0.05). Current-voltage relationship of
Fig 4. Whole-cell $I_{Na}$ in guinea pig ventricular myocytes. A) $I_{Na}$ traces before and after exposure to different concentrations of DDPH (20 – 320 μmol · L$^{-1}$). B) Percent change of $I_{Na}$ after mexiletine (○) ($n = 5$) and DDPH (●). $n = 9$. $\bar{x} \pm s$.

$I_{Na}$ was generated by applying depolarizing pulses from $-70$ mV to $+40$ mV for 200 ms with a 10-mV increment. DDPH 80 μmol · L$^{-1}$ decreased the $I_{Na}$ at $-30$ mV from $-7.3 \pm 1.7$ nA to $-2.9 \pm 2.0$ nA ($n = 6$ cells from 6 guinea pigs, $P < 0.01$) (Fig 5).

To test use-dependent blocking effect on $I_{Na}$ of DDPH, we evoked $I_{Na}$ with 10 repetitive pulses from $-80$ mV to $-30$ mV for 200 ms at two different frequencies; 1.0 and 3.0 Hz. The interval between the trains lasted 2 min. In the presence of DDPH 80 μmol · L$^{-1}$, there was a reduction of $I_{Na}$ during the first pulse (decrease by 46 ± 31 % at 1 Hz and 52 ± 22 % at 3 Hz, $n = 5$ cells from 5 guinea pigs, $P < 0.05$). But the $I_{Na}$ at the 10th pulse of the train had no difference between 1 Hz and 3 Hz, suggesting that DDPH could not block $I_{Na}$ in a use-dependent manner.

**DISCUSSION**

The major findings in our experiment were that DDPH could block both $I_{Ca}$ and $I_{Na}$ in guinea pig ventricular myocytes. Compared with verapamil and mexiletine, although the inhibitory potency of DDPH on $I_{Ca}$ and $I_{Na}$ was weaker than that of verapamil and mexiletine, it had a striking characteristics of blocking effects on multiple ion channel currents including $I_{K}$ and $I_{K1}$.$^{(7)}$ This property is now considered very important in the treatment of cardiac arrhythmias. It is suggested that an antiarrhythmic agent affecting multiple ion channels in a diseased heart may be favorable for cardiac arrhythmias and may hopefully reduce the incidence of proarrhythmias.$^{(10)}$ The inhibitory effects of DDPH on $I_{Ca}$, $I_{Na}$, $I_{K}$, and $I_{K1}$ indicated that it bore the pharmacologic properties of both verapamil and mexiletine. However, DDPH blocked multiple ion channel currents with different potencies. In our experiment, the $I_{Ca}$ value of $I_{K}$ was 89.0 μmol · L$^{-1}$, much larger than that of $I_{Ca}$ (28.5 μmol · L$^{-1}$). Zhong et al reported that DDPH inhibited $I_{K}$ with a $IC_{50}$ value of 13.3 (11.6 – 16.7) μmol · L$^{-1}$ and the inhibitory effects of DDPH on $I_{K}$ was more potent than those of $I_{K1}$. It is certain that DDPH inhibited $I_{Na}$ more weakly than $I_{K}$ and $I_{Ca}$. These results were supported by stan-

$\bar{x} \pm s$.
standard microelectrode studies showing that lower concentrations of DDPH altered the action potential duration without any changes of APA, $V_{\text{max}}$, or RP, while larger concentrations of DDPH shortened APA, prolonged $V_{\text{max}}$, and decreased APA or slowed $V_{\text{max}}$.

Since the chemical structure and the effects of DDPH are complicated, some studies such as to observe the effects and mechanism of its action in a diseased heart are needed for further investigation to elucidate its mechanism of antiarrhythmic action.
