ABSTRACT

AIM: To investigate the changes of cardiac calcium handling proteins and endothelin system in dilated cardiomyopathy (DCM) rats and the effects of perindopril and bisoprolol on the remodeling ventricles. METHODS: DCM rats were employed using a 2-kidney, 1-clip hypertensive and diabetic model. Some of the DCM rats were treated with perindopril and bisoprolol for 3 months, respectively. The ratio of left ventricular weight to body weight (LVW/BW), mRNA expressions of calcium handling proteins and endothelin receptors were determined. The alterations of maximum binding capacity ($B_{\text{max}}$) and equilibrium dissociation constant ($K_D$) values of cardiac endothelin receptors (ETR) and its subtypes were detected. RESULTS: Compared with those of normal control, blood pressure, and LVW/BW in the DCM rats were elevated. Sarcoplasmic reticulum calcium pump (SERCA) mRNA expression and SERCA activity decreased in the left ventricle. The ETR $B_{\text{max}}$ decreased, especially the endothelin receptor A. Endothelin converting enzyme activity and expression were elevated, and mRNA expressions of $\beta_1$-adrenoreceptor and inositol-3-phosphate receptor in some hearts increased as well. The administration of perindopril and bisoprolol could reverse myocardial hypertrophy and restore the imbalance of calcium handling proteins and endothelin system. CONCLUSION: The disorder of calcium handling proteins and endothelin system existed in the hearts of DCM rats. Treatment of perindopril and bisoprolol could reverse myocardial hypertrophy and changes in DCM rats.

INTRODUCTION

Dilated cardiomyopathy (DCM) is a myocardial disease characterized by progressive depression of myocardial contractile function and by ventricular dilation. The pathogenic mechanism of DCM is still not clear. In the present study, we measured the changes of cardiac calcium handling proteins and the endothelin system in left ventricular remodeling from DCM rats, and investigated the influences of $\beta$-blockers and inhibitor of angiotensin converting enzyme (ACE-I) on the regulation of intracellular calcium and endothelin system.

MATERIALS AND METHODS

DCM model and protocol The DCM model
adopted was the 2-kidney and 1-clip combined with diabetes rat (SD rats were obtained from Shanghai SIPPR/BK Limited Company, male, 160-180 g), which was a well established and widely used model[1] with a tail BP over 170 mmHg and blood glucose over 17.78 mmol/L. The DCM rats were divided into a DCM model group (D), a perindopril-treated DCM group (A, ACE-I 1 mg·kg⁻¹·d⁻¹) and a bisoprolol-treated DCM group (B, β₁ antagonist 0.83 mg·kg⁻¹·d⁻¹). Normal SD rats were housed as a control group (S). All rats were sacrificed after treatment for 3 months. The hearts and ventricles were immediately separated and weighted to determine the ratio of left ventricular weight to body weight (LVW/BW). The left ventricles were put into liquid nitrogen immediately, then stored at -75 ºC for further study.

**mRNA level** The mRNA levels of β₁-adrenoreceptor (β₁AR), L-Ca²⁺ channel, sarcoplasmatic reticulum calcium pump (SERCA), inositol-3-phosphate receptor type I (IP3-1R), angiotensin II receptor (AT1R), ryanodine receptor (RyR), endothelin receptor A (ETAR), endothelin receptor B (ETBR) and endothelin converting enzyme (ECE) in the left ventricles from the rats were determined by RT-PCR.

**SERCA and ECE activities** The activities of SERCA and ECE were determined following the methods of Larsen[2] and Ahn[3] respectively, with some modification.

**Maximum binding capacity (Bₘₐₓ) and equilibrium dissociation constant (Kₐ) of the endothelin receptor** The alterations of Bₘₐₓ and Kₐ of cardiac endothelin receptors (ETR) and its subtypes were detected by radio-ligand binding assay[4,5]. ET-1 (MERCA) was labeled by National Science Nuclear Institute (Beijing, China).

**Statistics** Data were expressed as mean±SD. n refers to the number of rats. Statistical analysis was performed using analysis of variance or Student’s t-test. A value of P<0.05 was considered to be significant.

**RESULTS**

**Systolic blood pressure (SBP) and LV/BW** The SBP and LV/BW of the DCM model group were significantly higher than those of the control group (P<0.05). Compared with those of DCM model group, the SBP and LVW/BW of perindopril-treated group decreased very significantly (P<0.05), the SBP of bisoprolol-treated group decreased as well (Tab 1).

**mRNA expression of membrane receptors and calcium handling proteins** The mRNA expression of β₁AR and IP₃₁R in model group was higher than that of control group (P<0.05). No significant differences in mRNA expressions of AT₁R, RyR and L-Ca²⁺ were found between control and DCM model group. Compared with those of DCM model group, the expression of β₁AR and IP₃₁R of perindopril-treated group was significantly lower (P<0.05). Meanwhile, in perindopril-treated group, the expressions of AT₁R and RyR reduced significantly (P<0.05), SERCA and L-Ca²⁺ channel unchanged. Compared with those of model group, the expressions of IP₃₁R, AT₁ R, RyR and L-Ca²⁺ of bisoprolol-treated group decreased, the β₁AR and

SERCA unchanged (Tab 2). The SERCA activity of model group was lower than that of control group significantly (2.656 ± 0.566 μmol·min⁻¹·g⁻¹ protein vs 1.652 ± 0.543 μmol·min⁻¹·g⁻¹ protein, P<0.01).

**Bₘₐₓ** and **Kₐₜ** values of cardiac ETR, ETₐR and ETₐR The ETR density (Bₘₐₓ) of the DCM model group decreased by 29% compared with the S group, and ETₐR was reduced by 33%. A slight tendency of ETₐR reduction was also observed in the same group. High ETR densities were observed in the perindopril-treated and bisoprolol-treated groups, which increased by 62% and 39% respectively compared with the DCM model group, P<0.05. The subtype of ETₐR showed a remarkable increase in the perindopril-treated and bisoprolol-treated groups. No significant differences were observed in ETₐR density when the perindopril-treated and bisoprolol-treated groups were compared with the model group (Tab 3).

**ETₐR and ETₐR mRNA expressions** The ETₐR mRNA level of left ventricles was markedly lower in the DCM model group than in the control group [(0.108±0.025) vs (0.20±0.06), P<0.05]. The ETₐR mRNA level was slightly attenuated, but not significantly [(0.296±0.013) vs (0.38±0.05), P>0.05]. The expressions of ETₐR and ETₐR mRNA in the perindopril-treated and bisoprolol-treated groups were both significantly increased compared with those of the DCM model group [ETₐR: (0.41±0.06) and (0.45±0.10), P<0.01; ETₐR: (0.55±0.04) and (0.79±0.26), P>0.05].

**mRNA expression and activity of ECE** Compared with that of the S group, the ECE mRNA expression of the DCM model group increased by (1.2±0.4) vs (0.7±0.3), P<0.01. The ECE expressions in the perindopril-treated and bisoprolol-treated groups were 0.98±0.02 and 0.73±0.24, respectively, which were remarkably lower than that of DCM model group, especially the bisoprolol-treated group (P<0.05). The ECE activities of the control, DCM model, perindopril-treated, and bisoprolol-treated groups were (42±10), (58±9), (22±6), and (60±12) pmol/L, respectively. The ECE activity of the DCM model group was markedly higher than those of control and bisoprolol-treated group (P<0.05), and was not different to that of the perindopril-treated group.

**DISCUSSION**

The hypertensive combined diabetic rat as DCM model has been used widely since the pathologic change in the heart is similar to that of human DCM[6]. Our data demonstrated that LVW/BW increased in the model group than that in the control group (P<0.05). The data revealed that left ventricular remodeling was occurring at 4 months, and regulations of calcium handling proteins and membrane receptors were injured in the myocardial cells. The activity and mRNA expression of SERCA decreased and IP₃-1R expression increased (by 8% and 44%, respectively), which would result in calcium accumulation in myocardial cells, since calcium pump density was decreased and the release channel density was increased. Chronic calcium overload in the myocardial cell has been well known to play an important role for tissue growth through stimulating protein kinase C pathway[7]. The mRNA expression of β₁-AR in the left ventricles of DCM rats increased by 3.6-fold compared to the control group. Previous data from our laboratory showed that Bₘₐₓ of β-AR increased about 40% with no change of the Kₐₜ value in left ventricles at the early stage of DCM[8]. Through stimulation of the cyclic adenosine monophosphate and kinase upregulation, β-AR would at least partially promote the hypertrophic process in the ventricle. Both the gene expression and the density of ETR were markedly attenuated in left ventricular of DCM rats. At the same
time both ECE expression and activity were elevated in DCM rats. The administration of perindopril and bisoprolol could at least partially reverse myocardial hypertrophy in DCM rats by lowering the mRNA expression of β₁-AR, AT₁R, IP₃R, RyR, and L-Ca²⁺ channel in the left ventricular and restoring the balance of calcium handling proteins and endothelin system. These changes in the calcium handling proteins and endothelin system indicated the existence of cross-talk among endothelial system, renin-angiotensin system, and beta-adrenergic system. The effects of each system could be strengthened by interacting with each other.
